

## OVERVIEW

The AA18375AP is a two-channel PWM DC-DC converter control IC that features low-voltage operation. This IC can obtain the step-up, step-down and inverting voltages with a small number of external components. Because the IC is compactly packaged, it is best suited for use as a power supply in portable equipment.

## FEATURES

- Wide supply voltage range: 3.6 V to 15 V
- Low current consumption: 1.3 mA typical
- Control in a wide output frequency range is possible (1 kHz to 500 kHz).
- Timer latch, short-circuit protection circuit is built in.
- Circuit to prevent malfunction during low input voltage is built in.
- Built-in reference voltage (1.28V) output pin.
- Dead time period is adjustable over the whole range of duty ratio.
- Synchronization operation is possible.

## PIN Configuration

(TOP VIEW)

C <sub>T</sub>	1	16	V <sub>REF</sub>
R <sub>T</sub>	2	15	SCP
+IN1	3	14	+IN2
-IN1	4	13	-IN2
FB1	5	12	FB2
D.T.C.1	6	11	D.T.C.2
OUT1	7	10	OUT2

**TYPICAL CHARACTERISTICS**

## OPERATION DESCRIPTION

### 1. Reference voltage

This block is composed of the band gap circuit, and outputs the temperature compensated 2.5 V reference from Vcc (pin 9) for use by internal circuits. A reference voltage of temperature compensated 1/2 Vref can be obtained to external circuit by Vref terminal (pin 16).

### 2. Oscillator

The sawtooth-waveform-like triangular wave having a peak of approximately 1.9 V and a trough of approximately 1.3 V can be generated by connecting the timing capacitor C<sub>T</sub> (pin 1) and resistor R<sub>T</sub> (pin 2). The usable oscillation frequency is from 1 kHz to the maximum 500 KHz. The triangular wave is connected with the non-inverting input of PWM comparator for channel 1 side and channel 2 side within the IC inside.

### 3. Error amplifiers

The output voltage of DC-DC converter is detected by the error-amplifier and the amplified signal is input to the PWM comparator. Also, it is possible to perform the gain setting and the phase compensation arbitrarily by connecting a resistor and a capacitor from the FB terminals (pins 5 and 12) to GND. The error amplifier output is internally connected to the inverting inputs of the PWM comparators and also to the short protection circuit.

### 4. Timer latch short protection circuit

This circuit protects the external main switching devices, flywheel diodes, and choke coils, etc. from destruction or deterioration if overload or short-circuit condition of power supply output lasts for a certain time. The timer latch short-circuit protection circuit detects the output level of the error amplifier. If one or both error amplifier outputs are 1.1 V or lower, the low-level output is given and the timer circuit is actuated to start the charge of the external protection-enable capacitor.

If the output level of the error amplifier does not drop below the normal voltage range before the capacitor voltage reaches the 1.19 V, it sets the latch circuit, and cuts off the output drive transistor, and sets the dead-time to 100%.

### 5. Under voltage lockout protection circuit

This circuit protects the system from destruction or deterioration due to control malfunction when the supply voltage is low in the transient state of power on/off. The under voltage lockout protection circuit compares the internal reference voltage level with the supply voltage level. If the supply voltage level falls below the reference level it cuts off the output drive transistor, and sets the dead time to 100%. The protection enable terminal (pin 15) is pulled "Low".

### 6. PWM comparator

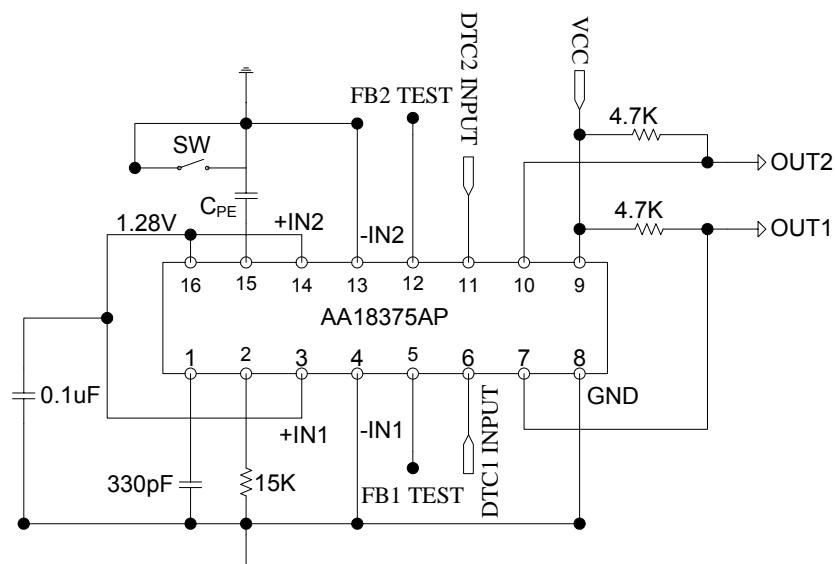

Each PWM comparator has two inverting inputs and one non-inverting input. This voltage-to-pulse-width converter controls the output pulse width according to the input voltage. The PWM comparator turns the output drive transistor on when the oscillator triangular waveform is higher than the error amplifier output and the dead time control terminal voltage.

### 7. Output drive transistor

This output circuit is open-collector type. The available output current is up to 50 mA. The breakdown voltage of output terminal is 15V.

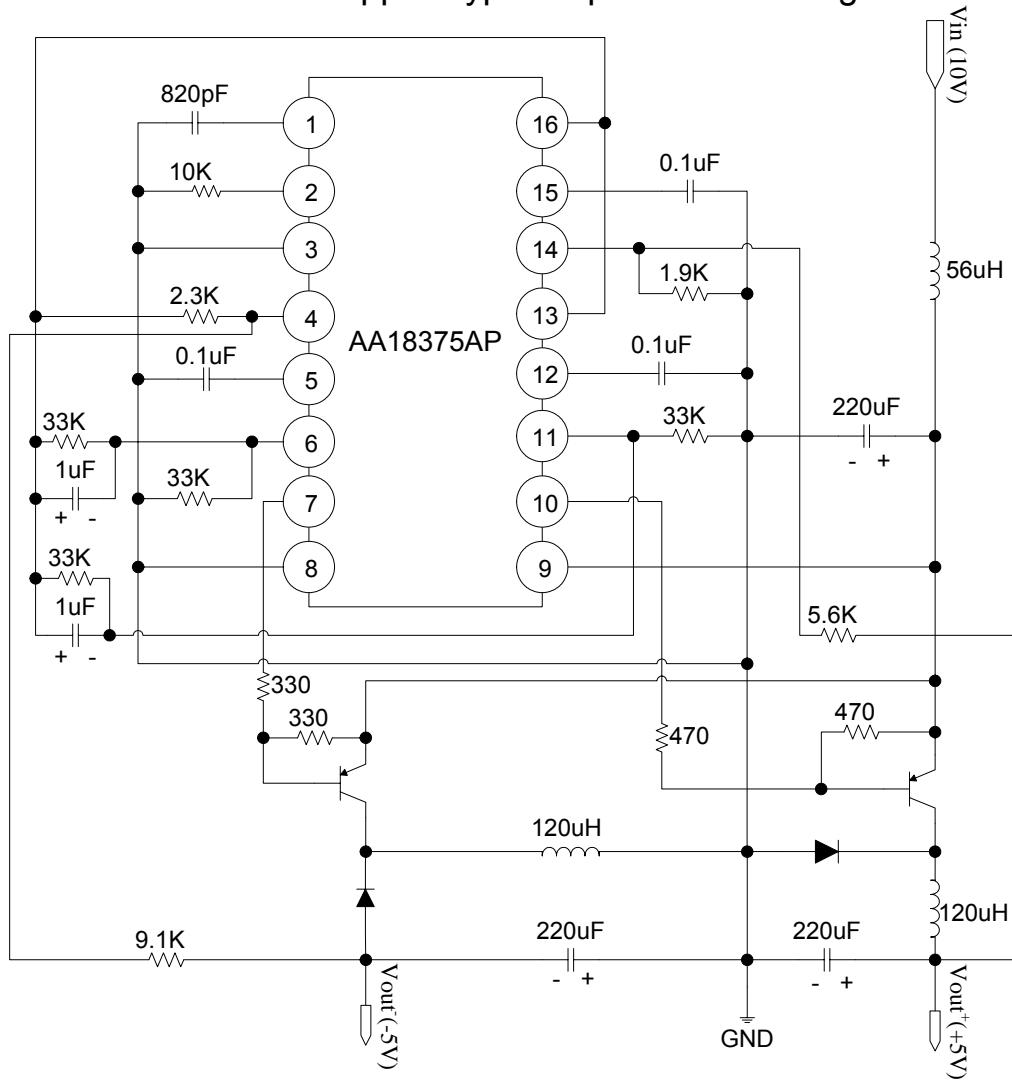

## TEST CIRCUIT

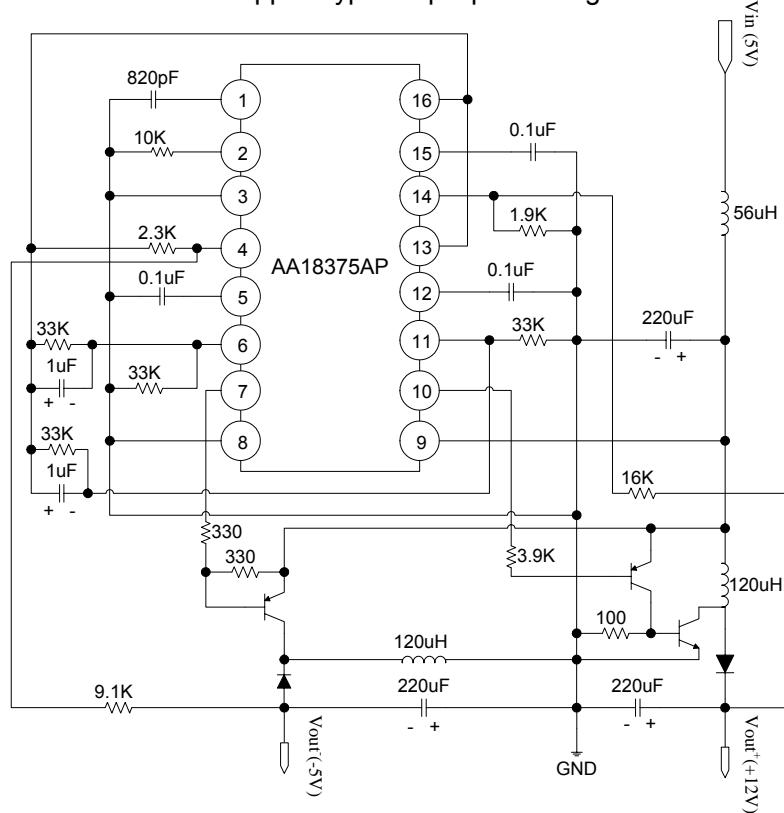

## TYPICAL APPLICATION EXAMPLE

## Chopper Type Step Down/Inverting

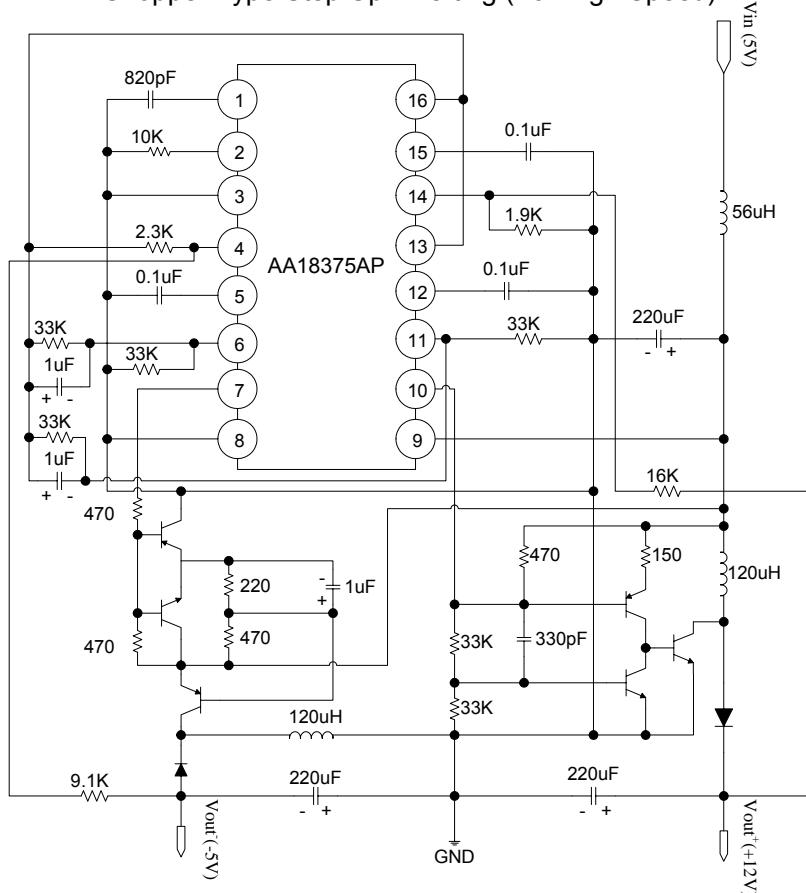

## Chopper Type Step Up/Inverting

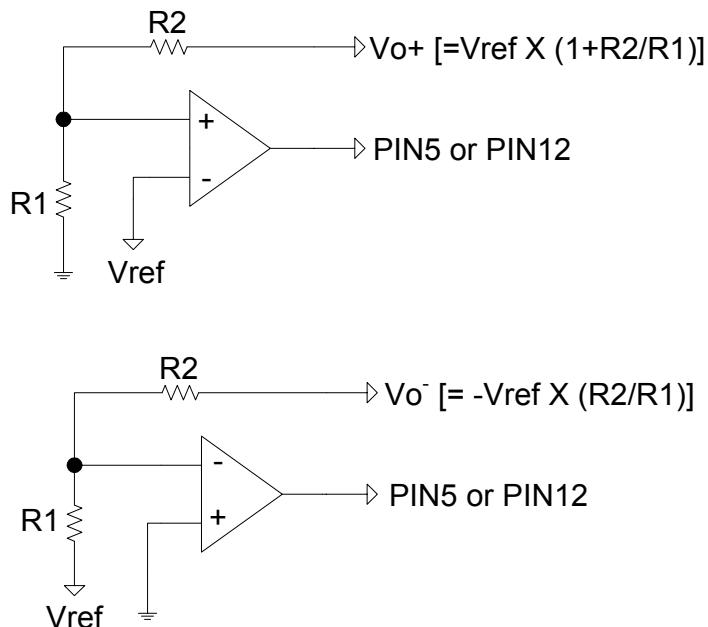

## Chopper Type Step Up/Inverting (For High Speed)

## HOW TO SET OUTPUT VOLTAGE

The output voltage is set using the connection shown below. The error amplifiers are supplied to the internal reference voltage circuit as are the other internal circuits. The common-mode input voltage range is from -0.2 V to +1.45 V. When the amplifiers are operated non-inverting, tie the inverting terminal to  $V_{REF}$  (1.28 V). When the amplifiers are operated inverting, tie the non-inverting terminal to ground.

## HOW TO SET TIME CONSTANT FOR TIMER LATCH SHORT PROTECTION CIRCUIT

If the load condition drastically changes due to a load short-circuit and if low-level signals (1.1 V or lower) are input to the non-inverting inputs of the short-circuit protection comparator from the error amplifiers, the short circuit protection comparator outputs a "Low" level. The protection enable terminal voltage is discharged, and then the short-circuit protection comparator charges the externally connected protection enable capacitor  $C_{PE}$  according to the following formula:

$$V_{PE} = 50 \text{ mV} + t_{PE} \times 10^{-6} / C_{PE}$$

$$0.65 = 50 \text{ mV} + t_{PE} \times 10^{-6} / C_{PE}$$

$$C_{PE} = t_{PE}/0.6 (\mu\text{F})$$

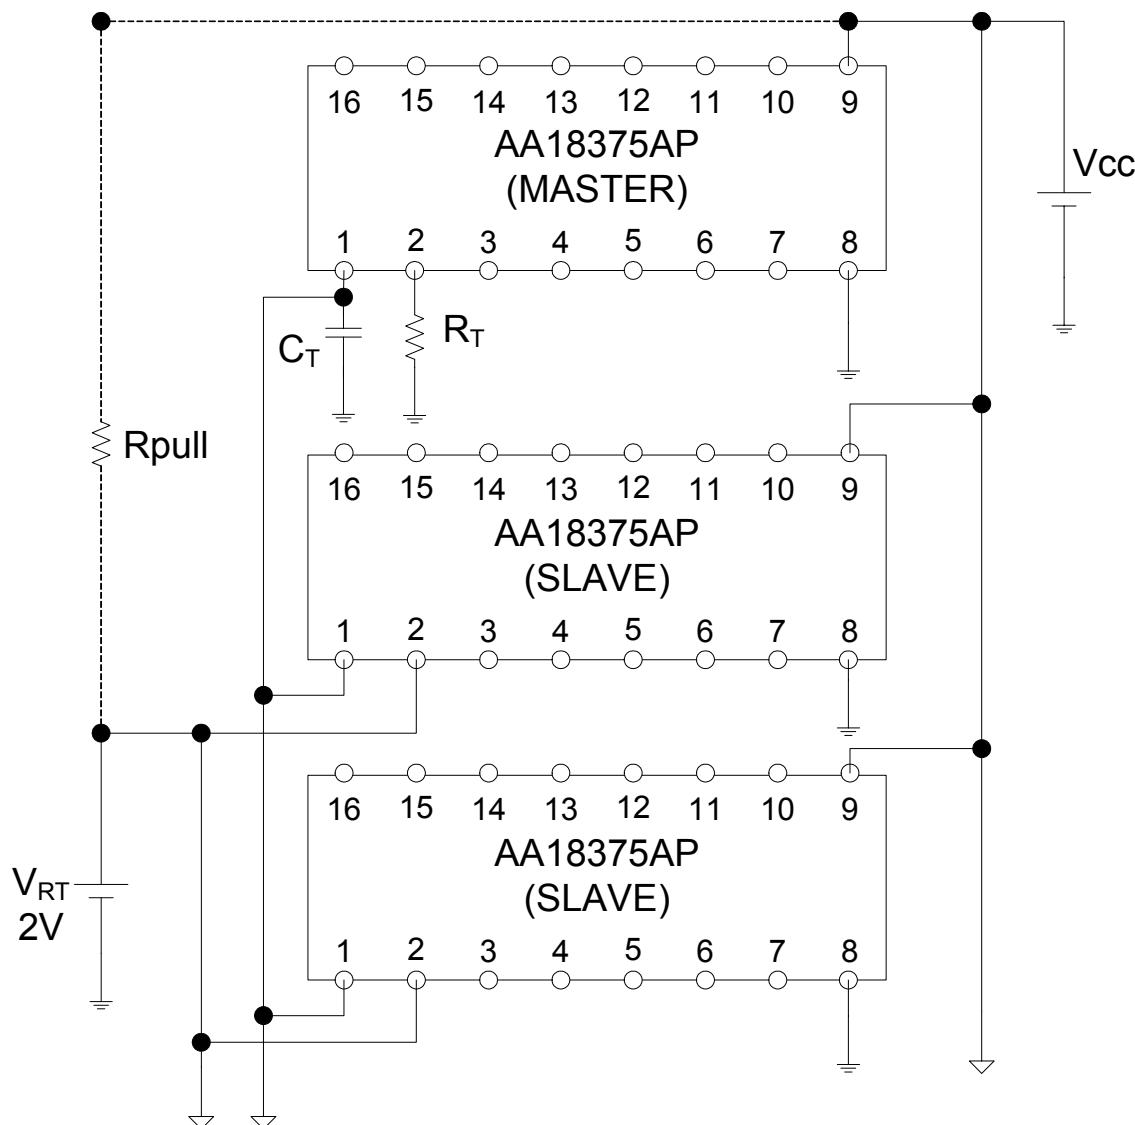

When the power supply is turned on, the output is considered to be short-circuited state so that the S.C.P. terminal voltage starts charging. It is necessary to set the external capacitor so as to start up the DC-DC converter output voltage before setting the latch circuit in the later stage. Especially, pay attention to the delay of the start-up time when applying the soft-start function.

### SYNCHRONIZATION OF ICs

Multiple instances of this IC can be operated in parallel. If the  $C_T$  and  $R_T$  terminals are connected to each other as shown below, the ICs will operate at the same frequency. Instead of applying  $V_{RT}$  to the  $R_T$  terminals, these terminals can be pulled up by a resistor (see resistance indicated by the dashed line in). Select the pull-up resistance  $R_{pull}$  from the formula given below.

$$\frac{V_{cc}}{0.5 \times N} \leq R_{pull}$$

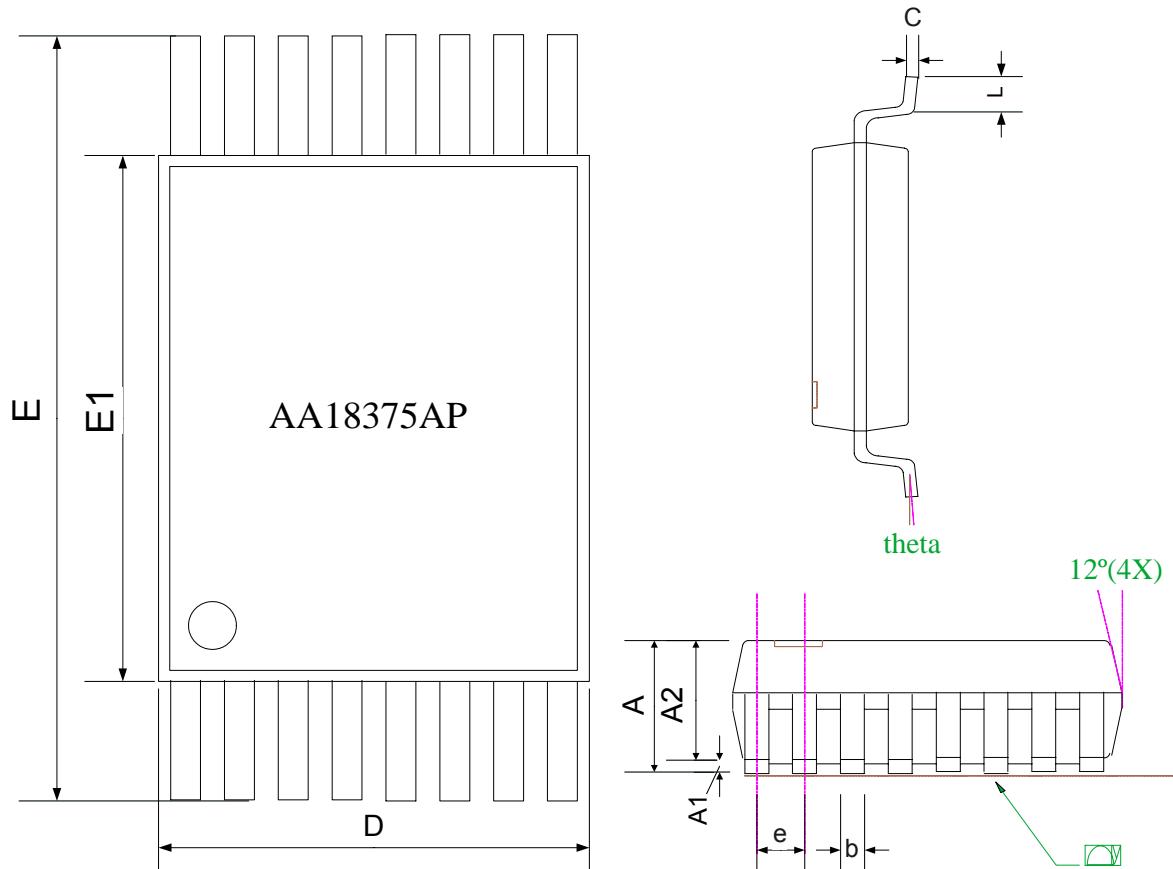

Rpull: Pull up Resistor (kΩ)  
VCC: Power Supply Voltage (V)  
N: Number of Slave ICs
