

Data Sheet

July 2003

The following document specifies Spansion memory products that are now offered by both Advanced Micro Devices and Fujitsu. Although the document is marked with the name of the company that originally developed the specification, these products will be offered to customers of both AMD and Fujitsu.

### **Continuity of Specifications**

There is no change to this datasheet as a result of offering the device as a Spansion product. Any changes that have been made are the result of normal datasheet improvement and are noted in the document revision summary, where supported. Future routine revisions will occur when appropriate, and changes will be noted in a revision summary.

### **Continuity of Ordering Part Numbers**

AMD and Fujitsu continue to support existing part numbers beginning with "Am" and "MBM". To order these products, please use only the Ordering Part Numbers listed in this document.

#### For More Information

Please contact your local AMD or Fujitsu sales office for additional information about Spansion memory solutions.

Publication Number 22326 Revision A Amendment +I Issue Date November 8, 2004

THIS PAGE LEFT INTENTIONALLY BLANK.

# 

# Am29DS163D

16 Megabit (2 M x 8-Bit/1 M x 16-Bit) CMOS 1.8 Volt-only, Simultaneous Operation Flash Memory

# **DISTINCTIVE CHARACTERISTICS**

#### ARCHITECTURAL ADVANTAGES

#### Simultaneous Read/Write operations

- Data can be continuously read from one bank while executing erase/program functions in other bank
- Zero latency between read and write operations

#### Multiple bank architectures

 Two devices available with different bank sizes (refer to Table 3)

#### Secured Silicon (SecSi) Sector

- Factory locked and identifiable: 16 bytes available for secure, random factory Electronic Serial Number; verifiable as factory locked through autoselect function. ExpressFlash option allows entire sector to be available for factory-secured data.
- Customer lockable: Can be read, programmed, or erased just like other sectors. Once locked, data cannot be changed.
- 64 Kbyte sector size

#### Zero Power Operation

- Sophisticated power management circuits reduce power consumed during inactive periods to nearly zero
- Package options
  - 48-ball FBGA
- Top or bottom boot block
- Manufactured on 0.23 µm process technology
- Compatible with JEDEC standards
  - Pinout and software compatible with single-power-supply flash standard

#### PERFORMANCE CHARACTERISTICS

#### High performance

- Access time as fast 100 ns
- Program time: 13 µs/word typical utilizing Accelerate function

#### Ultra low power consumption (typical values)

- 1 mA active read current at 1 MHz
- 5 mA active read current at 5 MHz
- 200 nA in standby or automatic sleep mode
- Minimum 1 million write cycles guaranteed per sector

20 Year data retention at 125°C
 — Reliable operation for the life of the system

#### SOFTWARE FEATURES

- Data Management Software (DMS)
  - AMD-supplied software manages data programming and erasing, enabling EEPROM emulation
  - Eases sector erase limitations
- Supports Common Flash Memory Interface (CFI)

#### Erase Suspend/Erase Resume

 Suspends erase operations to allow programming in same bank

#### Data# Polling and Toggle Bits

- Provides a software method of detecting the status of program or erase cycles
- Unlock Bypass Program command
  - Reduces overall programming time when issuing multiple program command sequences

#### HARDWARE FEATURES

- Any combination of sectors can be erased
- Ready/Busy# output (RY/BY#)
  - Hardware method for detecting program or erase cycle completion
- Hardware reset pin (RESET#)
  - Hardware method of resetting the internal state machine to reading array data

### WP#/ACC input pin

- Write protect (WP#) function allows protection of two outermost boot sectors, regardless of sector protect status
- Acceleration (ACC) function provides accelerated program times

#### Sector protection

- Hardware method of locking a sector, either in-system or using programming equipment, to prevent any program or erase operation within that sector
- Temporary Sector Unprotect allows changing data in protected sectors in-system

# **GENERAL DESCRIPTION**

The Am29DS163D family consists of 16 megabit, 1.8 volt-only flash memory devices, organized as 1,048,576 words of 16 bits each or 2,097,152 bytes of 8 bits each. Word mode data appears on DQ0–DQ15; byte mode data appears on DQ0–DQ7. The device is designed to be programmed in-system with the standard 1.8 volt  $V_{CC}$  supply, and can also be programmed in standard EPROM programmers.

The device is available with an access time of 100 and 120 ns. The devices are offered in an 48-ball FBGA package. Standard control pins—chip enable (CE#), write enable (WE#), and output enable (OE#)—control normal read and write operations, and avoid bus contention issues.

The device requires only a **single 1.8 volt power sup-ply** for both read and write functions. Internally generated and regulated voltages are provided for the program and erase operations.

# Simultaneous Read/Write Operations with Zero Latency

The Simultaneous Read/Write architecture provides **simultaneous operation** by dividing the memory space into two banks. The device can improve overall system performance by allowing a host system to program or erase in one bank, then immediately and simultaneously read from the other bank, with zero latency. This releases the system from waiting for the completion of program or erase operations.

# Am29DS163D Features

The Secured Silicon (SecSi) Sector is an additional 64 Kbyte sector capable of being permanently locked by AMD or customers. The SecSi Sector Indicator Bit (DQ7) is permanently set to a 1 if the part is factory locked, and set to a 0 if customer lockable. This way, customer lockable parts can never be used to replace a factory locked part.

Factory locked parts provide several options. The SecSi Sector may store a secure, random 16 byte ESN (Electronic Serial Number), customer code (programmed through AMD's ExpressFlash service), or both. Customer Lockable parts may utilize the SecSi Sector as bonus space, reading and writing like any other flash sector, or may permanently lock their own code there.

**DMS (Data Management Software)** allows systems to easily take advantage of the advanced architecture of the simultaneous read/write product line by allowing

removal of EEPROM devices. DMS also allows the system software to be simplified, as it performs all functions necessary to modify data in file structures, as opposed to single-byte modifications. To write or update a particular piece of data (a phone number or configuration data, for example), the user only needs to state which piece of data is to be updated, and where the updated data is located in the system. This is an advantage compared to systems where user-written software must keep track of the old data location, status, logical to physical translation of the data onto the Flash memory device (or memory devices), and more. Using DMS, user-written software does not need to interface with the Flash memory directly. Instead, the user's software accesses the Flash memory by calling one of only six functions. AMD provides this software to simplify system design and software integration efforts.

The device offers complete compatibility with the **JEDEC single-power-supply Flash command set standard**. Commands are written to the command register using standard microprocessor write timings. Reading data out of the device is similar to reading from other Flash or EPROM devices.

The host system can detect whether a program or erase operation is complete by using the device **status bits:** RY/BY# pin, DQ7 (Data# Polling) and DQ6/DQ2 (toggle bits). After a program or erase cycle is completed, the device automatically returns to reading array data.

The **sector erase architecture** allows memory sectors to be erased and reprogrammed without affecting the data contents of other sectors. The device is fully erased when shipped from the factory.

Hardware data protection measures include a low  $V_{CC}$  detector that automatically inhibits write operations during power transitions. The hardware sector protection feature disables both program and erase operations in any combination of the sectors of memory. This is achieved in-system or via programming equipment.

The device offers two power-saving features. When addresses are stable for a specified amount of time, the device enters the **automatic sleep mode**. The system can also place the device into the **standby mode**. Power consumption is greatly reduced in both modes.

# Special Handling Instructions for FBGA Package

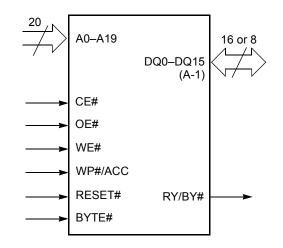

Special handling is required for Flash Memory products in FBGA packages. Flash memory devices in FBGA packages may be damaged if exposed to ultrasonic cleaning methods. The package and/or data integrity may be compromised if the package body is exposed to temperatures above 150°C for prolonged periods of time.

### **ORDERING INFORMATION**

# **Standard Products**

AMD standard products are available in several packages and operating ranges. The order number (Valid Combination) is formed by a combination of the following:

1.8 Volt-only Read, Program, and Erase

#### Valid Combinations

Valid Combinations list configurations planned to be supported in volume for this device. Consult the local AMD sales office to confirm availability of specific valid combinations and to check on newly released combinations.

# **DEVICE BUS OPERATIONS**

This section describes the requirements and use of the device bus operations, which are initiated through the internal command register. The command register itself does not occupy any addressable memory location. The register is a latch used to store the commands, along with the address and data information needed to execute the command. The contents of the register serve as inputs to the internal state machine. The state machine outputs dictate the function of the device. Table 1 lists the device bus operations, the inputs and control levels they require, and the resulting output. The following subsections describe each of these operations in further detail.

|                            |                            |     |     |                            |          |                               |                  | DQ8–DQ15                   |                            |  |  |  |  |

#### Table 1. Am29DS163D Device Bus Operations

**Legend:**  $L = Logic Low = V_{IL}$ ,  $H = Logic High = V_{IH}$ ,  $V_{ID} = 9.0-11.0$  V,  $V_{HH} = 9.0 \pm 0.5$  V, X = Don't Care, SA = Sector Address,  $A_{IN} = Address In$ ,  $D_{IN} = Data In$ ,  $D_{OUT} = Data Out$ 

Notes:

- 1. Addresses are A19:A0 in word mode (BYTE# =  $V_{IH}$ ), A19:A-1 in byte mode (BYTE# =  $V_{IL}$ ).
- 2. The sector protect and sector unprotect functions may also be implemented via programming equipment. See "Sector/Sector Block Protection and Unprotection" on page 16.
- If WP#/ACC = V<sub>IL</sub>, the two outermost boot sectors remain protected. If WP#/ACC = V<sub>IH</sub>, the two outermost boot sector protection depends on whether they were last protected or unprotected using the method described in "Sector/Sector Block Protection and Unprotection" on page 16. If WP#/ACC = V<sub>HH</sub>, all sectors are unprotected.

# Word/Byte Configuration

The BYTE# pin controls whether the device data I/O pins operate in the byte or word configuration. If the BYTE# pin is set at logic '1', the device is in word configuration, DQ0–DQ15 are active and controlled by CE# and OE#.

If the BYTE# pin is set at logic '0', the device is in byte configuration, and only data I/O pins DQ0–DQ7 are active and controlled by CE# and OE#. The data I/O pins DQ8–DQ14 are tri-stated, and the DQ15 pin is used as an input for the LSB (A-1) address function.

# **Requirements for Reading Array Data**

To read array data from the outputs, the system must drive the CE# and OE# pins to  $V_{IL}$ . CE# is the power control and selects the device. OE# is the output control and gates array data to the output pins. WE# should remain at  $V_{IH}$ . The BYTE# pin determines whether the device outputs array data in words or bytes.

The internal state machine is set for reading array data upon device power-up, or after a hardware reset. This ensures that no spurious alteration of the memory content occurs during the power transition. No command is necessary in this mode to obtain array data. Standard microprocessor read cycles that assert valid addresses on the device address inputs produce valid data on the device data outputs. Each bank remains enabled for read access until the command register contents are altered.

See "Requirements for Reading Array Data" on page 10 for more information. Refer to the Table on page 36 for timing specifications and to Figure 13, on page 36 for the timing diagram.  $I_{CC1}$  in the DC Characteristics table represents the active current specification for reading array data.

# Writing Commands/Command Sequences

To write a command or command sequence (which includes programming data to the device and erasing sectors of memory), the system must drive WE# and CE# to  $V_{IL}$ , and OE# to  $V_{IH}$ .

For program operations, the BYTE# pin determines whether the device accepts program data in bytes or words. Refer to "Word/Byte Configuration" on page 10 for more information.

The device features an **Unlock Bypass** mode to facilitate faster programming. Once a bank enters the Unlock Bypass mode, only two write cycles are required to program a word or byte, instead of four. The "Word/Byte Configuration" section contains details on programming data to the device using both standard and Unlock Bypass command sequences.

An erase operation can erase one sector, multiple sectors, or the entire device. Table 3 on page 13 to Table 6 on page 14 indicate the address space that each sector occupies. The device address space is divided into two banks: Bank 1 contains the boot/parameter sectors, and Bank 2 contains the larger, code sectors of uniform size. A "bank address" is the address bits required to uniquely select a bank. Similarly, a "sector address" is the address bits required to uniquely select a sector.

 $I_{CC2}$  in the DC Characteristics table represents the active current specification for the write mode. The "AC Characteristics" on page 36 section contains timing specification tables and timing diagrams for write operations.

### **Accelerated Program Operation**

The device offers accelerated program operations through the ACC function. This is one of two functions provided by the WP#/ACC pin. This function is primarily intended to allow faster manufacturing throughput at the factory.

If the system asserts  $V_{HH}$  on this pin, the device automatically enters the aforementioned Unlock Bypass mode, temporarily unprotects any protected sectors, and uses the higher voltage on the pin to reduce the time required for program operations. The system

would use a two-cycle program command sequence as required by the Unlock Bypass mode. Removing  $V_{HH}$  from the WP#/ACC pin returns the device to normal operation. Note that the WP#/ACC pin must not be at  $V_{HH}$  for operations other than accelerated programming, or device damage may result. In addition, the WP#/ACC pin must not be left floating or unconnected; inconsistent behavior of the device may result.

#### **Autoselect Functions**

If the system writes the autoselect command sequence, the device enters the autoselect mode. The system can then read autoselect codes from the internal register (which is separate from the memory array) on DQ7–DQ0. Standard read cycle timings apply in this mode. Refer to "Autoselect Mode" on page 15 and "Autoselect Command Sequence" on page 23 for more information.

# Simultaneous Read/Write Operations with Zero Latency

This device is capable of reading data from one bank of memory while programming or erasing in the other bank of memory. An erase operation may also be suspended to read from or program to another location within the same bank (except the sector being erased). Figure 20, on page 42 shows how read and write cycles may be initiated for simultaneous operation with zero latency.  $I_{CC6}$  and  $I_{CC7}$  in the DC Characteristics table represent the current specifications for read-while-program and read-while-erase, respectively.

# Standby Mode

When the system is not reading or writing to the device, it can place the device in the standby mode. In this mode, current consumption is greatly reduced, and the outputs are placed in the high impedance state, independent of the OE# input.

The device enters the CMOS standby mode when the CE# and RESET# pins are both held at  $V_{CC} \pm 0.3$  V. (Note that this is a more restricted voltage range than  $V_{IH}$ .) If CE# and RESET# are held at  $V_{IH}$ , but not within  $V_{CC} \pm 0.3$  V, the device is in the standby mode, but the standby current is greater. The device requires standard access time ( $t_{CE}$ ) for read access when the device is in either of these standby modes, before it is ready to read data.

If the device is deselected during erasure or programming, the device draws active current until the operation is completed.

 ${\sf I}_{{\sf CC3}}$  in the DC Characteristics table represents the standby current specification.

# **Automatic Sleep Mode**

The automatic sleep mode minimizes Flash device energy consumption. The device automatically enables this mode when addresses remain stable for  $t_{ACC}$  + 30 ns. The automatic sleep mode is independent of the CE#, WE#, and OE# control signals. Standard address access timings provide new data when addresses are changed. While in sleep mode, output data is latched and always available to the system.  $I_{CC4}$  in the "DC Characteristics" on page 33 represents the automatic sleep mode current specification.

## **RESET#: Hardware Reset Pin**

The RESET# pin provides a hardware method of resetting the device to reading array data. When the RESET# pin is driven low for at least a period of  $t_{RP}$ , the device immediately terminates any operation in progress, tristates all output pins, and ignores all read/write commands for the duration of the RESET# pulse. The device also resets the internal state machine to reading array data. The operation that was interrupted should be reinitiated once the device is ready to accept another command sequence, to ensure data integrity.

Current is reduced for the duration of the RESET# pulse. When RESET# is held at  $V_{SS}\pm0.3$  V, the device draws CMOS standby current ( $I_{CC4}$ ). If RESET# is held

at  $V_{\text{IL}}$  but not within  $V_{\text{SS}} \pm 0.3$  V, the standby current is greater.

The RESET# pin may be tied to the system reset circuitry. A system reset would thus also reset the Flash memory, enabling the system to read the boot-up firmware from the Flash memory.

If RESET# is asserted during a program or erase operation, the RY/BY# pin remains a "0" (busy) until the internal reset operation is complete, which requires a time of  $t_{READY}$  (during Embedded Algorithms). The system can thus monitor RY/BY# to determine whether the reset operation is complete. If RESET# is asserted when a program or erase operation is not executing (RY/BY# pin is "1"), the reset operation is completed within a time of  $t_{READY}$  (not during Embedded Algorithms). The system can read data  $t_{RH}$  after the RESET# pin returns to V<sub>IH</sub>.

Refer to "AC Characteristics" on page 36 for RESET# parameters and to Figure 14, on page 37 for the timing diagram.

## **Output Disable Mode**

When the OE# input is at  $V_{IH}$ , output from the device is disabled. The output pins are placed in the high impedance state.

| Device      |          | Bank 1  |          | Bank 2                           |
|-------------|----------|---|----------|----------------------------------|

## Autoselect Mode

The autoselect mode provides manufacturer and device identification, and sector protection verification, through identifier codes output on DQ7–DQ0. This mode is primarily intended for programming equipment to automatically match a device to be programmed with its corresponding programming algorithm. However, the autoselect codes can also be accessed in-system through the command register.

When using programming equipment, the autoselect mode requires  $V_{ID}$  (9.0 V to 11.0 V) on address pin A9. Address pins A6, A1, and A0 must be as shown in

Table 7. In addition, when verifying sector protection, the sector address must appear on the appropriate highest order address bits (see Tables 3–6). Table 7 shows the remaining address bits that are don't care. When all necessary bits are set as required, the programming equipment may then read the corresponding identifier code on DQ7–DQ0.

To access the autoselect codes in-system, the host system can issue the autoselect command via the command register, as shown in Table 14. This method does not require  $V_{\rm ID}$ . Refer to the Autoselect Command Sequence section for more information.

# Sector/Sector Block Protection and Unprotection

(Note: For the following discussion, the term "sector" applies to both sectors and sector blocks. A sector block consists of two or more adjacent sectors that are protected or unprotected at the same time (see Tables 8 and 9).

The hardware sector protection feature disables both program and erase operations in any sector. The hardware sector unprotection feature re-enables both program and erase operations in previously protected sectors. Sector protection and unprotection can be implemented via two methods.

The primary method requires  $V_{ID}$  on the RESET# pin only, and can be implemented either in-system or via programming equipment. Figure 2 shows the algorithms and Figure 25 shows the timing diagram. This method uses standard microprocessor bus cycle timing. For sector unprotect, all unprotected sectors must first be protected prior to the first sector unprotect write cycle. The alternate method intended only for programming equipment requires  $V_{ID}$  on address pin A9 and OE#. This method is compatible with programmer routines written for earlier 1.8 volt-only AMD flash devices. Contact an AMD representative for further details.

The device is shipped with all sectors unprotected. AMD offers the option of programming and protecting sectors at its factory prior to shipping the device through AMD's ExpressFlash<sup>™</sup> Service. Contact an AMD representative for details.

It is possible to determine whether a sector is protected or unprotected. See the Autoselect Mode section for details.

# Write Protect (WP#)

The Write Protect function provides a hardware method of protecting certain boot sectors without using  $V_{\text{ID}}$ . This function is one of two provided by the WP#/ACC pin.

If the system asserts  $V_{IL}$  on the WP#/ACC pin, the device disables program and erase functions in the two "outermost" 8 Kbyte boot sectors independently of whether those sectors were protected or unprotected using the method described in "Sector/Sector Block Protection and Unprotection". The two outermost 8 Kbyte boot sectors are the two sectors containing the lowest addresses in a bottom-boot-configured device, or the two sectors containing the highest addresses in a top-boot-configured device.

If the system asserts  $V_{IH}$  on the WP#/ACC pin, the device reverts to whether the two outermost 8 Kbyte boot sectors were last set to be protected or unprotected. That is, sector protection or unprotection for these two sectors depends on whether they were last protected or unprotected using the method described in "Sector/Sector Block Protection and Unprotection".

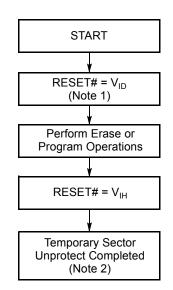

Note that the WP#/ACC pin must not be left floating or unconnected; inconsistent behavior of the device may result.

# **Temporary Sector/Sector Block Unprotect**

(Note: For the following discussion, the term "sector" applies to both sectors and sector blocks. A sector

block consists of two or more adjacent sectors that are protected or unprotected at the same time (see Tables 8 and 9).

This feature allows temporary unprotection of previously protected sectors to change data in-system. The Sector Unprotect mode is activated by setting the RE-SET# pin to  $V_{ID}$  (9.0 – 11.0 V). During this mode, formerly protected sectors can be programmed or erased by selecting the sector addresses. Once  $V_{ID}$  is removed from the RESET# pin, all the previously protected sectors are protected again. Figure 1 shows the algorithm, and Figure 24 shows the timing diagrams, for this feature.

#### Notes:

- All protected sectors unprotected (If WP#/ACC = V<sub>IL</sub>, outermost boot sectors will remain protected).
- 2. All previously protected sectors are protected once again.

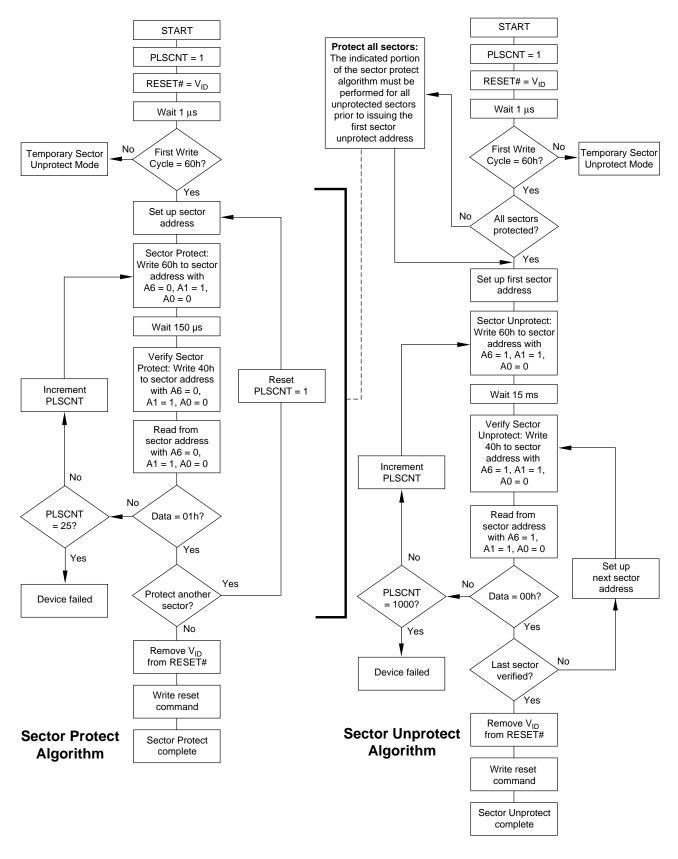

Figure 2. In-System Sector/Sector Block Protect and Unprotect Algorithms

### SecSi (Secured Silicon) Sector Flash Memory Region

The SecSi (Secured Silicon) Sector feature provides an additional 64Kbyte Flash memory region that enables permanent part identification through an Electronic Serial Number (ESN). An SecSi Sector Indicator Bit indicates whether or not the SecSi Sector is locked when shipped from the factory. This bit is permanently set at the factory and cannot be changed, which prevents cloning of a factory locked part. This ensures the security of the ESN once the product is shipped to the field.

AMD offers the device with the SecSi Sector either factory locked or customer lockable. The factory-locked version is always protected when shipped from the factory, and the SecSi Sector Indicator Bit is permanently set to a "1." The customer-lockable version is shipped with the unprotected, allowing customers to utilize the that sector in any manner they choose. In the customer-lockable version, the SecSi Sector Indicator Bit is permanently set to a "0." Thus, the SecSi Sector Indicator Bit prevents customer-lockable devices from being used to replace devices that are factory locked.

The system accesses the SecSi Sector through a command sequence (see "Enter SecSi Sector/Exit SecSi Sector Command Sequence" on page 24). After the system writes the Enter SecSi Sector command sequence, it may read the SecSi Sector by using the addresses normally occupied by the boot sectors. This mode of operation continues until the system issues the Exit SecSi Sector command sequence, or until power is removed from the device. On power-up, or following a hardware reset, the device reverts to sending commands to the boot sectors.

The following restrictions apply to using the SecSi Sector: Once the device enters the SecSi Sector, any attempt to initiate program or erase operations in the array is ignored until the device exits the SecSi Sector. Conversely, when a program or erase operation in the array is in progress, the device ignores any attempt to enter the SecSi Sector until programming or erasing is complete.

# Factory Locked: SecSi Sector Programmed and Protected at the Factory

In a factory locked device, the SecSi Sector is protected when the device is shipped from the factory. The SecSi Sector cannot be modified in any way. The device is available preprogrammed with one of the following:

- A random, secure ESN only
- Customer code through the ExpressFlash service
- Both a random, secure ESN and customer code through the ExpressFlash service.

In devices that have an ESN, a Bottom Boot device has the 16-byte ESN at addresses 00000h–00007h in word mode (or 000000h–00000Fh in byte mode). In the Top Boot device the starting address of the ESN is at addresses F8000h–F8007h in word mode (or 1F0000h–1F000Fh in byte mode).

Customers may opt to have their code programmed by AMD through the AMD ExpressFlash service. AMD programs the customer's code, with or without the random ESN. The devices are then shipped from AMD's factory with the permanently locked. Contact an AMD representative for details on using AMD's Express-Flash service.

#### Customer Lockable: SecSi Sector NOT Programmed or Protected at the Factory

If the security feature is not required, the SecSi Sector can be treated as an additional Flash memory space, expanding the size of the available Flash array by 64 Kbytes. The SecSi Sector can be read, programmed, and erased as often as required. The SecSi Sector area can be protected using one of the following procedures:

- Write the three-cycle Enter SecSi Sector Region command sequence, and then follow the in-system sector protect algorithm as shown in Figure 2, except that *RESET# may be at either V<sub>IH</sub> or V<sub>ID</sub>*. This allows in-system protection of the without raising any device pin to a high voltage. Note that this method is only applicable to the SecSi Sector.
- Write the three-cycle Enter SecSi Sector Region command sequence, and then use the alternate method of sector protection described in "Sector/Sector Block Protection and Unprotection" on page 16.

Once the SecSi Sector is locked and verified, the system must write the Exit SecSi Sector Region command sequence to return to reading and writing the remainder of the array.

The SecSi Sector protection must be used with caution since, once protected, there is no procedure available for unprotecting the SecSi Sector area and none of the bits in the SecSi Sector memory space can be modified in any way. Note also that the multiple program and erase capability of the customer lockable version of this device may be subject to change on future device revisions.

# **Hardware Data Protection**

The command sequence requirement of unlock cycles for programming or erasing provides data protection against inadvertent writes (refer to Table 14 on page 27 for command definitions). In addition, the following hardware data protection measures prevent accidental erasure or programming, which might otherwise be caused by spurious system level signals during  $V_{\text{CC}}$  power-up and power-down transitions, or from system noise.

#### Low V<sub>CC</sub> Write Inhibit

When  $V_{CC}$  is less than  $V_{LKO}$ , the device does not accept any write cycles. This protects data during  $V_{CC}$  power-up and power-down. The command register and all internal program/erase circuits are disabled, and the device resets to reading array data. Subsequent writes are ignored until  $V_{CC}$  is greater than  $V_{LKO}$ . The system must provide the proper signals to the control pins to prevent unintentional writes when  $V_{CC}$  is greater than  $V_{LKO}$ .

#### Write Pulse "Glitch" Protection

Noise pulses of less than 5 ns (typical) on OE#, CE# or WE# do not initiate a write cycle.

#### Logical Inhibit

Write cycles are inhibited by holding any one of OE# =  $V_{IL}$ , CE# =  $V_{IH}$  or WE# =  $V_{IH}$ . To initiate a write cycle, CE# and WE# must be a logical zero while OE# is a logical one.

#### **Power-Up Write Inhibit**

If WE# = CE# =  $V_{IL}$  and OE# =  $V_{IH}$  during power up, the device does not accept commands on the rising edge of WE#. The internal state machine is automatically reset to reading array data on power-up.

# COMMON FLASH MEMORY INTERFACE (CFI)

The Common Flash Interface (CFI) specification outlines device and host system software interrogation handshake, which allows specific vendor-specified software algorithms to be used for entire families of devices. Software support can then be device-independent, JEDEC ID-independent, and forward- and backward-compatible for the specified flash device families. Flash vendors can standardize their existing interfaces for long-term compatibility.

This device enters the CFI Query mode when the system writes the CFI Query command, 98h, to address 55h in word mode (or address AAh in byte mode), any time the device is ready to read array data. The system can read CFI information at the addresses given in Table 10 on page 20 to Table 13 on page 22. To terminate reading CFI data, the system must write the reset command.

The system can also write the CFI query command when the device is in the autoselect mode. The device enters the CFI query mode, and the system can read CFI data at the addresses given in Table 10 on page 20 to Table 13 on page 22. The system must write the reset command to return the device to the autoselect mode.

For further information, please refer to the CFI Specification and CFI Publication 100, available via the World Wide Web at http://www.amd.com/products/nvd/overview/cfi.html. Alternatively, contact an AMD representative for copies of these documents.

Note:

The number of sectors in Bank 2 is device dependent. Am29DS163 = 18h

### **COMMAND DEFINITIONS**

Writing specific address and data commands or sequences into the command register initiates device operations. Table 14 on page 27 defines the valid register command sequences. Writing **incorrect address and data values** or writing them in the **improper sequence** resets the device to reading array data.

All addresses are latched on the falling edge of WE# or CE#, whichever happens later. All data is latched on the rising edge of WE# or CE#, whichever happens first. Refer to the AC Characteristics section for timing diagrams.

## **Reading Array Data**

The device is automatically set to reading array data after device power-up. No commands are required to retrieve data. Each bank is ready to read array data after completing an Embedded Program or Embedded Erase algorithm.

After the device accepts an Erase Suspend command, the corresponding bank enters the erase-suspend-read mode, after which the system can read data from any non-erase-suspended sector within the same bank. After completing a programming operation in the Erase Suspend mode, the system may once again read array data with the same exception. See the "Erase Suspend/Erase Resume Commands" on page 26 section for more information.

The system *must* issue the reset command to return a bank to the read (or erase-suspend-read) mode if DQ5 goes high during an active program or erase operation, or if the bank is in the autoselect mode. See the next section, "Reset Command", for more information.

See also "Requirements for Reading Array Data" on page 10 for more information. Table on page 36 provides the read parameters, and Figure 13, on page 36 shows the timing diagram.

### **Reset Command**

Writing the reset command resets the banks to the read or erase-suspend-read mode. Address bits are don't cares for this command.

The reset command may be written between the sequence cycles in an erase command sequence before erasing begins. This resets the bank to which the system was writing to reading array data. Once erasure begins, however, the device ignores reset commands until the operation is complete.

The reset command may be written between the sequence cycles in a program command sequence before programming begins. This resets the bank to which the system was writing to reading array data. If the program command sequence is written to a bank that is in the Erase Suspend mode, writing the reset

command returns that bank to the erase-suspend-read mode. Once programming begins, however, the device ignores reset commands until the operation is complete.

The reset command may be written between the sequence cycles in an autoselect command sequence. Once in the autoselect mode, the reset command must be written to return to reading array data. If a bank entered the autoselect mode while in the Erase Suspend mode, writing the reset command returns that bank to the erase-suspend-read mode.

If DQ5 goes high during a program or erase operation, writing the reset command returns the banks to reading array data (or erase-suspend-read mode if that bank was in Erase Suspend).

## Autoselect Command Sequence

The autoselect command sequence allows the host system to access the manufacturer and device codes, and determine whether or not a sector is protected. Table 14 on page 27 shows the address and data requirements. This method is an alternative to that shown in Table 7 on page 15, which is intended for PROM programmers and requires  $V_{ID}$  on address pin A9. The autoselect command sequence may be written to an address within a bank that is either in the read or erase-suspend-read mode. The autoselect command may not be written while the device is actively programming or erasing in the other bank.

The autoselect command sequence is initiated by first writing two unlock cycles. This is followed by a third write cycle that contains the bank address and the autoselect command. The bank then enters the autoselect mode. The system may read at any address within the same bank any number of times without initiating another autoselect command sequence. The following table describes the hex address requirements for the various autoselect functions, and the resulting data. BA represents the bank address, and SA represents the sector address.

| Description                        | Word<br>Address | Byte<br>Address | Read Data*                                     |
|------------------------------------|-----------------|-----------------|--|
| Manufacturer<br>ID                 | (BA) + 00       | (BA) + 00       | 01   |
| Device ID                          | (BA) + 01       | (BA) + 02       | 2295 (top boot)<br>2296 (bottom boot)          |
| Sector Block<br>Protect Verify     | (SA) + 02       | (SA) + 04       | 00 (unlocked),<br>01 (locked)                  |
| SecSi Sector<br>Factory<br>Protect | (BA) + 03       | (BA) + 06       | 85 (factory locked)<br>05 (not factory locked) |

\* For byte mode, ignore data output bits D8–DQ15.

The system must write the reset command to return to reading array data (or erase-suspend-read mode if the bank was previously in Erase Suspend).

# Enter SecSi Sector/Exit SecSi Sector Command Sequence

The system can access the SecSi Sector region by issuing the three-cycle Enter SecSi Sector command sequence. The device continues to access the SecSi Sector region until the system issues the four-cycle Exit SecSi Sector command sequence. The Exit SecSi Sector command sequence returns the device to normal operation. Table 14 on page 27 shows the address and data requirements for both command sequences. See also "SecSi (Secured Silicon) Sector Flash Memory Region" on page 19 for further information. Note that a hardware reset (RESET#=V<sub>IL</sub>) resets the device to reading array data.

# **Byte/Word Program Command Sequence**

The system may program the device by word or byte, depending on the state of the BYTE# pin. Programming is a four-bus-cycle operation. The program command sequence is initiated by writing two unlock write cycles, followed by the program set-up command. The program address and data are written next, which in turn initiate the Embedded Program algorithm. The system is *not* required to provide further controls or timings. The device automatically provides internally generated program pulses and verifies the programmed cell margin. Table 14 on page 27 shows the address and data requirements for the byte program command sequence.

When the Embedded Program algorithm is complete, that bank then returns to reading array data and addresses are no longer latched. The system can determine the status of the program operation by using DQ7, DQ6, or RY/BY#. Refer to "Write Operation Status" on page 28 for information on these status bits.

Any commands written to the device during the Embedded Program Algorithm are ignored. Note that a **hardware reset** immediately terminates the program operation. The program command sequence should be reinitiated once that bank returns to reading array data, to ensure data integrity.

Programming is allowed in any sequence and across sector boundaries. A bit cannot be programmed from "0" back to a "1." Attempting to do so may cause that bank to set DQ5 = 1, or cause the DQ7 and DQ6 status bits to indicate the operation was successful. However, a succeeding read shows that the data is still "0." Only erase operations can convert a "0" to a "1."

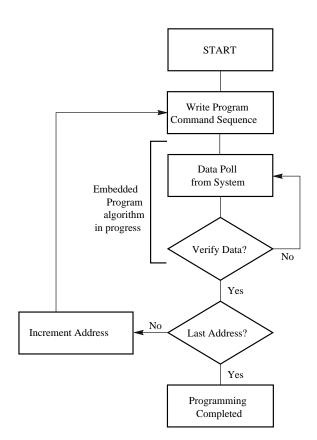

#### **Unlock Bypass Command Sequence**

The unlock bypass feature allows the system to program bytes or words to a bank faster than using the standard program command sequence. The unlock bypass command sequence is initiated by first writing two unlock cycles. This is followed by a third write cycle containing the unlock bypass command, 20h. That bank then enters the unlock bypass mode. A two-cycle unlock bypass program command sequence is all that is required to program in this mode. The first cycle in this sequence contains the unlock bypass program command, A0h; the second cycle contains the program address and data. Additional data is programmed in the same manner. This mode dispenses with the initial two unlock cycles required in the standard program command sequence, resulting in faster total programming time. Table 14 on page 27 shows the requirements for the command sequence.

During the unlock bypass mode, only the Unlock Bypass Program and Unlock Bypass Reset commands are valid. To exit the unlock bypass mode, the system must issue the two-cycle unlock bypass reset command sequence. The first cycle must contain the bank address and the data 90h. The second cycle need only contain the data 00h. The bank then returns to the reading array data.

The device offers accelerated program operations through the WP#/ACC pin. When the system asserts  $V_{HH}$  on the WP#/ACC pin, the device automatically enters the Unlock Bypass mode. The system may then write the two-cycle Unlock Bypass program command sequence. The device uses the higher voltage on the WP#/ACC pin to accelerate the operation. Note that the WP#/ACC pin must not be at  $V_{HH}$  any operation other than accelerated programming, or device damage may result. In addition, the WP#/ACC pin must not be left floating or unconnected; inconsistent behavior of the device may result.

Figure 3, on page 25 illustrates the algorithm for the program operation. Refer to the "Erase and Program Operations" on page 39 for parameters, and Figure 17, on page 40 for timing diagrams.

Note: See Table 14 for program command sequence.

# **Chip Erase Command Sequence**

Chip erase is a six bus cycle operation. The chip erase command sequence is initiated by writing two unlock cycles, followed by a set-up command. Two additional unlock write cycles are then followed by the chip erase command, which in turn invokes the Embedded Erase algorithm. The device does *not* require the system to preprogram prior to erase. The Embedded Erase algorithm automatically preprograms and verifies the entire memory for an all zero data pattern prior to electrical erase. The system is not required to provide any controls or timings during these operations. Table 14 shows the address and data requirements for the chip erase command sequence.

When the Embedded Erase algorithm is complete, that bank returns to reading array data and addresses are no longer latched. The system can determine the status of the erase operation by using DQ7, DQ6, DQ2, or RY/BY#. Refer to the Write Operation Status section for information on these status bits. Any commands written during the chip erase operation are ignored. However, note that a **hardware reset** immediately terminates the erase operation. If that occurs, the chip erase command sequence should be reinitiated once that bank returns to reading array data, to ensure data integrity.

Figure 4, on page 26 illustrates the algorithm for the erase operation. Refer to the "Erase and Program Operations" on page 39 tables in the AC Characteristics section for parameters, and Figure 19, on page 41 section for timing diagrams.

# Sector Erase Command Sequence

Sector erase is a six bus cycle operation. The sector erase command sequence is initiated by writing two unlock cycles, followed by a set-up command. Two additional unlock cycles are written, and are then followed by the address of the sector to be erased, and the sector erase command. Table 14 on page 27 shows the address and data requirements for the sector erase command sequence.

The device does *not* require the system to preprogram prior to erase. The Embedded Erase algorithm automatically programs and verifies the entire memory for an all zero data pattern prior to electrical erase. The system is not required to provide any controls or timings during these operations.

After the command sequence is written, a sector erase time-out of 50 µs occurs. During the time-out period, additional sector addresses and sector erase commands may be written. Loading the sector erase buffer may be done in any sequence, and the number of sectors may be from one sector to all sectors. The time between these additional cycles must be less than 50 µs, otherwise erasure may begin. Any sector erase address and command following the exceeded time-out may or may not be accepted. It is recommended that processor interrupts be disabled during this time to ensure all commands are accepted. The interrupts can be re-enabled after the last Sector Erase command is written. Any command other than Sector Erase or Erase Suspend during the time-out period resets that bank to reading array data. The system must rewrite the command sequence and any additional addresses and commands.

The system can monitor DQ3 to determine if the sector erase timer timed out (See the section on "DQ3: Sector Erase Timer" on page 30.). The time-out begins from the rising edge of the final WE# pulse in the command sequence.

When the Embedded Erase algorithm is complete, the bank returns to reading array data and addresses are no longer latched. Note that while the Embedded Erase operation is in progress, the system can read data from the non-erasing bank. The system can determine the status of the erase operation by reading DQ7, DQ6, DQ2, or RY/BY# in the erasing bank. Refer to "Write Operation Status" on page 28 for information on these status bits.

AMDЛ

Once the sector erase operation starts, only the Erase Suspend command is valid. All other commands are ignored. However, note that a **hardware reset** immediately terminates the erase operation. If that occurs, the sector erase command sequence should be reinitiated once that bank returns to reading array data, to ensure data integrity.

Figure 4 illustrates the algorithm for the erase operation. Refer to the "Erase and Program Operations" on page 39 for parameters, and Figure 19, on page 41 section for timing diagrams.

# Erase Suspend/Erase Resume Commands

The Erase Suspend command, B0h, allows the system to interrupt a sector erase operation and then read data from, or program data to, any sector not selected for erasure. The bank address is required when writing this command. This command is valid only during the sector erase operation, including the 50  $\mu$ s time-out period during the sector erase command sequence. The Erase Suspend command is ignored if written during the chip erase operation or Embedded Program algorithm.

When the Erase Suspend command is written during the sector erase operation, the device requires a maximum of 20  $\mu$ s to suspend the erase operation. However, when the Erase Suspend command is written during the sector erase time-out, the device immediately terminates the time-out period and suspends the erase operation.

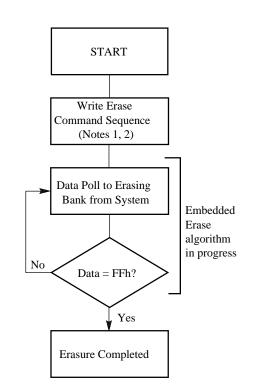

After the erase operation is suspended, the bank enters the erase-suspend-read mode. The system can read data from or program data to any sector not selected for erasure. (The device "erase suspends" all sectors selected for erasure.) Reading at any address within erase-suspended sectors produces status information on DQ7–DQ0. The system can use DQ7, or DQ6 and DQ2 together, to determine if a sector is actively erasing or is erase-suspended. Refer to the "Write Operation Status" on page 28 section for information on these status bits.

After an erase-suspended program operation is complete, the bank returns to the erase-suspend-read

mode. The system can determine the status of the program operation using the DQ7 or DQ6 status bits, just as in the standard Byte Program operation. Refer to the "Write Operation Status" on page 28 section for more information.

In the erase-suspend-read mode, the system can also issue the autoselect command sequence. Refer to the "Autoselect Mode" on page 15 and "Autoselect Command Sequence" on page 23 sections for details.

To resume the sector erase operation, the system must write the Erase Resume command. The bank address of the erase-suspended bank is required when writing this command. Further writes of the Resume command are ignored. Another Erase Suspend command can be written after the chip resumes erasing.

#### Notes:

- 1. See Table 14 on page 27 for erase command sequence.
- 2. See the section on DQ3 for information on the sector erase timer.

#### Figure 4. Erase Operation

#### Table 14. Am29DS163D Command Definitions

#### Legend:

X = Don't care

RA = Address of the memory location to be read.

RD = Data read from location RA during read operation.

*PA* = Address of the memory location to be programmed. Addresses latch on the falling edge of the WE# or CE# pulse, whichever happens later.

#### Notes:

- 1. See Table 1 on page 10 for description of bus operations.
- 2. All values are in hexadecimal.
- 3. Except for the read cycle and the fourth cycle of the autoselect command sequence, all bus cycles are write cycles.
- Data bits DQ15–DQ8 are don't care in command sequences, except for RD and PD.
- 5. Unless otherwise noted, address bits A19-A11 are don't cares.
- No unlock or command cycles required when bank is in read mode.
- 7. The Reset command is required to return to reading array data (or to the erase-suspend-read mode if previously in Erase Suspend) when a bank is in the autoselect mode, or if DQ5 goes high (while the bank is providing status information).
- The fourth cycle of the autoselect command sequence is a read cycle. The system must provide the bank address to obtain the manufacturer ID, device ID, or SecSi Sector factory protect information. Data bits DQ15–DQ8 are don't care. See the "Autoselect Command Sequence" on page 23 section for more information.

PD = Data to be programmed at location PA. Data latches on the rising edge of WE# or CE# pulse, whichever happens first.

SA = Address of the sector to be verified (in autoselect mode) or erased. Address bits A19–A12 uniquely select any sector. BA = Address of the bank that is being switched to autoselect mode, is in bypass mode, or is being erased.

- 9. The data is 85h for factory locked and 05h for not factory locked.
- 10. The data is 00h for an unprotected sector/sector block and 01h for a protected sector/sector block.
- 11. The Unlock Bypass command is required prior to the Unlock Bypass Program command.
- The Unlock Bypass Reset command is required to return to reading array data when the bank is in the unlock bypass mode.
- 13. The system may read and program in non-erasing sectors, or enter the autoselect mode, when in the Erase Suspend mode. The Erase Suspend command is valid only during a sector erase operation, and requires the bank address.
- 14. The Erase Resume command is valid only during the Erase Suspend mode, and requires the bank address.
- 15. Command is valid when device is ready to read array data or when device is in autoselect mode.

# WRITE OPERATION STATUS

The device provides several bits to determine the status of a program or erase operation: DQ2, DQ3, DQ5, DQ6, and DQ7. Table 15 on page 31 and the following subsections describe the function of these bits. DQ7 and DQ6 each offer a method for determining whether a program or erase operation is complete or in progress. The device also provides a hardware-based output signal, RY/BY#, to determine whether an Embedded Program or Erase operation is in progress or is completed.

### DQ7: Data# Polling

The Data# Polling bit, DQ7, indicates to the host system whether an Embedded Program or Erase algorithm is in progress or completed, or whether a bank is in Erase Suspend. Data# Polling is valid after the rising edge of the final WE# pulse in the command sequence.

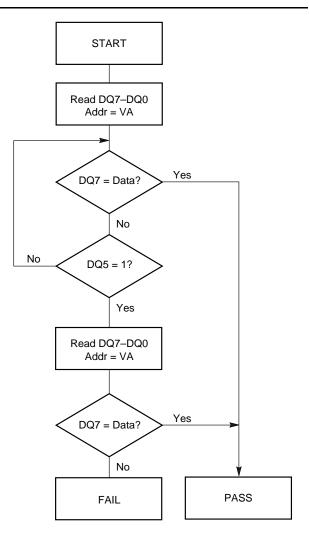

During the Embedded Program algorithm, the device outputs on DQ7 the complement of the datum programmed to DQ7. This DQ7 status also applies to programming during Erase Suspend. When the Embedded Program algorithm is complete, the device outputs the datum programmed to DQ7. The system must provide the program address to read valid status information on DQ7. If a program address falls within a protected sector, Data# Polling on DQ7 is active for approximately 1  $\mu$ s, then that bank returns to reading array data.

During the Embedded Erase algorithm, Data# Polling produces a "0" on DQ7. When the Embedded Erase algorithm is complete, or if the bank enters the Erase Suspend mode, Data# Polling produces a "1" on DQ7. The system must provide an address within any of the sectors selected for erasure to read valid status information on DQ7.

After an erase command sequence is written, if all sectors selected for erasing are protected, Data# Polling on DQ7 is active for approximately 100  $\mu$ s, then the bank returns to reading array data. If not all selected sectors are protected, the Embedded Erase algorithm erases the unprotected sectors, and ignores the selected sectors that are protected. However, if the system reads DQ7 at an address within a protected sector, the status may not be valid.

Just prior to the completion of an Embedded Program or Erase operation, DQ7 may change asynchronously with DQ0–DQ6 while Output Enable (OE#) is asserted low. That is, the device may change from providing status information to valid data on DQ7. Depending on when the system samples the DQ7 output, it may read the status or valid data. Even if the device completes the program or erase operation and DQ7 contains valid data, the data outputs on DQ0–DQ6 may be still invalid. Valid data on DQ0–DQ7 appears on successive read cycles.

Table 15 on page 31 shows the outputs for Data# Polling on DQ7. Figure 5 shows the Data# Polling algorithm. Figure 21, on page 42 shows the Data# Polling timing diagram.

#### Notes:

- VA = Valid address for programming. During a sector erase operation, a valid address is any sector address within the sector being erased. During chip erase, a valid address is any non-protected sector address.
- 2. DQ7 should be rechecked even if DQ5 = "1" because DQ7 may change simultaneously with DQ5.

#### Figure 5. Data# Polling Algorithm

#### RY/BY#: Ready/Busy#

The RY/BY# is a dedicated, open-drain output pin which indicates whether an Embedded Algorithm is in progress or complete. The RY/BY# status is valid after the rising edge of the final WE# pulse in the command sequence. Since RY/BY# is an open-drain output, several RY/BY# pins can be tied together in parallel with a pull-up resistor to  $V_{CC}$ .

If the output is low (Busy), the device is actively erasing or programming. (This includes programming in the Erase Suspend mode.) If the output is high (Ready), the device is reading array data, the standby mode, or one of the banks is in the erase-suspend-read mode.

Table 15 on page 31 shows the outputs for RY/BY#.

## DQ6: Toggle Bit I

Toggle Bit I on DQ6 indicates whether an Embedded Program or Erase algorithm is in progress or complete, or whether the device enters the Erase Suspend mode. Toggle Bit I may be read at any address, and is valid after the rising edge of the final WE# pulse in the command sequence (prior to the program or erase operation), and during the sector erase time-out.

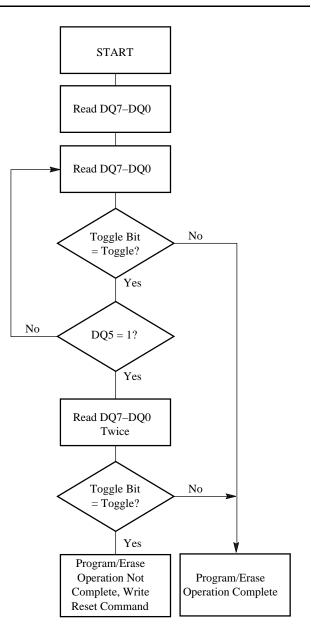

During an Embedded Program or Erase algorithm operation, successive read cycles to any address cause DQ6 to toggle. The system may use either OE# or CE# to control the read cycles. When the operation is complete, DQ6 stops toggling.

After an erase command sequence is written, if all sectors selected for erasing are protected, DQ6 toggles for approximately 100  $\mu$ s, then returns to reading array data. If not all selected sectors are protected, the Embedded Erase algorithm erases the unprotected sectors, and ignores the selected sectors that are protected.

The system can use DQ6 and DQ2 together to determine whether a sector is actively erasing or is erase-suspended. When the device is actively erasing (that is, the Embedded Erase algorithm is in progress), DQ6 toggles. When the device enters the Erase Suspend mode, DQ6 stops toggling. However, the system must also use DQ2 to determine which sectors are erasing or erase-suspended. Alternatively, the system can use DQ7 (see the subsection on DQ7: Data# Polling).

If a program address falls within a protected sector, DQ6 toggles for approximately 1  $\mu$ s after the program command sequence is written, then returns to reading array data.

DQ6 also toggles during the erase-suspend-program mode, and stops toggling once the Embedded Program algorithm is complete. Table 15 on page 31 shows the outputs for Toggle Bit I on DQ6. Figure 6 shows the toggle bit algorithm. Figure 22, on page 43 shows the toggle bit timing diagrams. Figure 23, on page 43 shows the differences between DQ2 and DQ6 in graphical form. See also the subsection on "DQ2: Toggle Bit II" on page 30.

**Note:** The system should recheck the toggle bit even if DQ5 = "1" because the toggle bit may stop toggling as DQ5 changes to "1." See the subsections on DQ6 and DQ2 for more information.

# DQ2: Toggle Bit II

The "Toggle Bit II" on DQ2, when used with DQ6, indicates whether a particular sector is actively erasing (that is, the Embedded Erase algorithm is in progress), or whether that sector is erase-suspended. Toggle Bit II is valid after the rising edge of the final WE# pulse in the command sequence.

DQ2 toggles when the system reads at addresses within those sectors that were selected for erasure. (The system may use either OE# or CE# to control the read cycles.) But DQ2 cannot distinguish whether the sector is actively erasing or is erase-suspended. DQ6, by comparison, indicates whether the device is actively erasing, or is in Erase Suspend, but cannot distinguish which sectors are selected for erasure. Thus, both status bits are required for sector and mode information. Refer to Table 15 on page 31 to compare outputs for DQ2 and DQ6.

Figure 6, on page 29 shows the toggle bit algorithm in flowchart form, and the section "DQ2: Toggle Bit II" explains the algorithm. See also the "DQ6: Toggle Bit I" on page 29 subsection. Figure 22, on page 43 shows the toggle bit timing diagram. Figure 23, on page 43 shows the differences between DQ2 and DQ6 in graphical form.

# Reading Toggle Bits DQ6/DQ2

Refer to Figure 6, on page 29 for the following discussion. Whenever the system initially begins reading toggle bit status, it must read DQ7–DQ0 at least twice in a row to determine whether a toggle bit is toggling. Typically, the system would note and store the value of the toggle bit after the first read. After the second read, the system would compare the new value of the toggle bit with the first. If the toggle bit is not toggling, the device completed the program or erase operation. The system can read array data on DQ7–DQ0 on the following read cycle.

However, if after the initial two read cycles, the system determines that the toggle bit is still toggling, the system also should note whether the value of DQ5 is high (see the section on DQ5). If it is, the system should then determine again whether the toggle bit is toggling, since the toggle bit may have stopped toggling just as DQ5 went high. If the toggle bit is no longer toggling, the device successfully completed the program or erase operation. If it is still toggling, the device did not completed the operation successfully, and the system must write the reset command to return to reading array data.

The remaining scenario is that the system initially determines that the toggle bit is toggling and DQ5 did not go high. The system may continue to monitor the toggle bit and DQ5 through successive read cycles, determining the status as described in the previous paragraph. Alternatively, it may choose to perform other system tasks. In this case, the system must start at the beginning of the algorithm when it returns to determine the status of the operation (top of Figure 6, on page 29).

# **DQ5: Exceeded Timing Limits**

DQ5 indicates whether the program or erase time exceeded a specified internal pulse count limit. Under these conditions DQ5 produces a "1," indicating that the program or erase cycle was not successfully completed.

The device may output a "1" on DQ5 if the system tries to program a "1" to a location that was previously programmed to "0." **Only an erase operation can change a "0" back to a "1."** Under this condition, the device halts the operation, and when the timing limit is exceeded, DQ5 produces a "1."

Under both these conditions, the system must write the reset command to return to reading array data (or to the erase-suspend-read mode if a bank was previously in the erase-suspend-program mode).

# **DQ3: Sector Erase Timer**

After writing a sector erase command sequence, the system may read DQ3 to determine whether or not erasure started. (The sector erase timer does not apply to the chip erase command.) If additional sectors are selected for erasure, the entire time-out also applies after each additional sector erase command. When the time-out period is complete, DQ3 switches from a "0" to a "1." If the time between additional sector erase commands from the system can be assumed to be less than 50 µs, the system need not monitor DQ3. See also "Sector Erase Command Sequence" on page 25.

After the sector erase command is written, the system should read the status of DQ7 (Data# Polling) or DQ6 (Toggle Bit I) to ensure that the device accepted the command sequence, and then read DQ3. If DQ3 is "1," the Embedded Erase algorithm started; all further commands (except Erase Suspend) are ignored until the erase operation is complete. If DQ3 is "0," the device accepts additional sector erase commands. To ensure the command is accepted, the system software should check the status of DQ3 prior to and following each subsequent sector erase command. If DQ3 is high on the second status check, the last command might not have been accepted.

Table 15 on page 31 shows the status of DQ3 relativeto the other status bits.

|                 | Status                   |                               | DQ7<br>(Note 2) | DQ6       | DQ5<br>(Note 1) | DQ3       | DQ2<br>(Note 2) | RY/BY# |
|-----------------|--------------------------|-------------------------------|-----------------|-----------|-----------------|-----------|-----------------|--------|

#### Table 15. Write Operation Status

Notes:

1. DQ5 switches to '1' when an Embedded Program or Embedded Erase operation exceeds the maximum timing limits. Refer to the section on DQ5 for more information.

2. DQ7 and DQ2 require a valid address when reading status information. Refer to the appropriate subsection for further details.

3. When reading write operation status bits, the system must always provide the bank address where the Embedded Algorithm is in progress. The device outputs array data if the system addresses a non-busy bank.

# **ABSOLUTE MAXIMUM RATINGS**

| Storage Temperature<br>Plastic Packages65°C to +150°C   |
|---|
| Ambient Temperature<br>with Power Applied65°C to +125°C |
| Voltage with Respect to Ground                          |
| $V_{CC}$ (Note 1)                                       |
| A9, OE#, and RESET#                                     |
| (Note 2)  |
| WP#/ACC   |
| All other pins (Note 1) –0.5 V to $V_{CC}$ +0.5 V       |
| Output Short Circuit Current (Note 3) 100 mA            |
|   |

#### Notes:

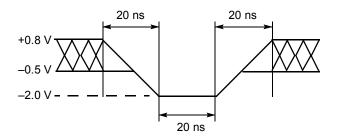

- 1. Minimum DC voltage on input or I/O pins is -0.5 V. During voltage transitions, input or I/O pins may overshoot V<sub>SS</sub> to -2.0 V for periods of up to 20 ns. Maximum DC voltage on input or I/O pins is V<sub>CC</sub> +0.5 V. See Figure 7. During voltage transitions, input or I/O pins may overshoot to V<sub>CC</sub> +2.0 V for periods up to 20 ns. See Figure 8.
- Minimum DC input voltage on pins A9, OE#, RESET#, and WP#/ACC is -0.5 V. During voltage transitions, A9, OE#, WP#/ACC, and RESET# may overshoot V<sub>SS</sub> to -2.0 V for periods of up to 20 ns. See Figure 7. Maximum DC input voltage on pin A9 is +12.5 V which may overshoot to +14.0 V for periods up to 20 ns. Maximum DC input voltage on WP#/ACC is +9.5 V which may overshoot to +12.0 V for periods up to 20 ns.
- No more than one output may be shorted to ground at a time. Duration of the short circuit should not be greater than one second.

Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only; functional operation of the device at these or any other conditions above those indicated in the operational sections of this data sheet is not implied. Exposure of the device to absolute maximum rating conditions for extended periods may affect device reliability.

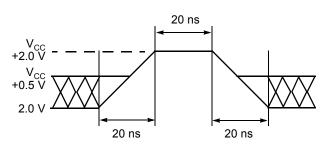

# **OPERATING RANGES**

| Commercial (C) Devices   |
|--|
| Ambient Temperature $(T_A)$ 0°C to +70°C                               |
| Industrial (I) Devices   |
| Ambient Temperature (T <sub>A</sub> )                                  |
| Extended (E) Devices   |
| Ambient Temperature (T <sub>A</sub> ) –55°C to +125°C                  |
| V <sub>cc</sub> Supply Voltages  |
| $V_{CC}$ for standard voltage range $\ldots\ldots\ldots1.8$ V to 2.2 V |
|  |

Operating ranges define those limits between which the functionality of the device is guaranteed.

#### Notes:

1. The  $I_{CC}$  current listed is typically less than 1 mA/MHz, with OE# at  $V_{IH}$ .

2. Maximum  $I_{CC}$  specifications are tested with  $V_{CC} = V_{CC}max$ .

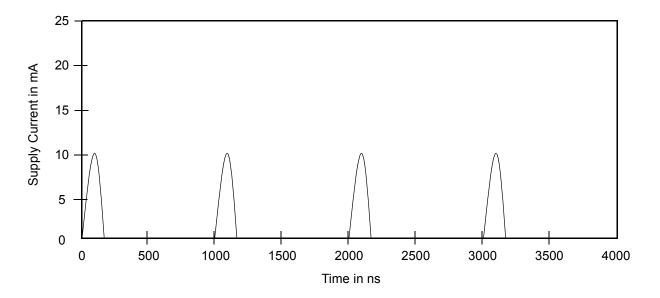

3. I<sub>CC</sub> active while Embedded Erase or Embedded Program is in progress.

Automatic sleep mode enables the low power mode when addresses remain stable for t<sub>ACC</sub> + 30 ns. Typical sleep mode current is 200 nA.

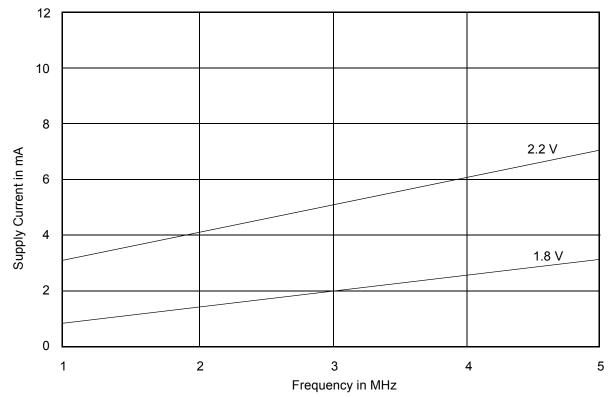

5. Not 100% tested.

#### Notes:

1. Not 100% tested.

2. See "Erase And Programming Performance" on page 48 for more information.

#### Notes:

- 1. Figure indicates last two bus cycles of a program or erase operation.
- 2. PA = program address, SA = sector address, PD = program data.
- 3. DQ7# is the complement of the data written to the device. D<sub>OUT</sub> is the data written to the device.
- 4. Waveforms are for the word mode.

#### Figure 26. Alternate CE# Controlled Write (Erase/Program) Operation Timings

### ERASE AND PROGRAMMING PERFORMANCE

| Parameter                          | Typ (Note 1) | Max (Note 2) | Unit | Comments                  |  |
|------------------------------------|--------------|--------------|------|---------------------------|--|
| Sector Erase Time                  | 2            | 15           | sec  | Excludes 00h programming  |  |
| Chip Erase Time                    | 78           |              | sec  | prior to erasure (Note 4) |  |
| Byte Program Time                  | 9            | 270          | μs   |                           |  |
| Word Program Time                  | 13           | 340          | μs   |                           |  |
| Accelerated Byte/Word Program Time |              | 7            | 210  | μs                        | Excludes system level<br>overhead (Note 5) |
| Chip Program Time                  | Byte Mode    | 28           | 80   |                           |  |
| (Note 3)                           | Word Mode    | 14           | 40   | sec                       |  |

Notes:

1. Typical program and erase times assume the following conditions: 25°C, 2.0 V V<sub>CC</sub>, 1,000,000 cycles. Additionally, programming typicals assume checkerboard pattern.

- 2. Under worst case conditions of  $90^{\circ}$ C, V<sub>CC</sub> = 2.2 V, 1,000,000 cycles.
- 3. The typical chip programming time is considerably less than the maximum chip programming time listed, since most bytes program faster than the maximum program times listed.
- 4. In the pre-programming step of the Embedded Erase algorithm, all bytes are programmed to 00h before erasure.
- 5. System-level overhead is the time required to execute the two- or four-bus-cycle sequence for the program command. See Table 14 on page 27 for further information on command definitions.
- 6. The device has a minimum erase and program cycle endurance of 1,000,000 cycles.

## LATCHUP CHARACTERISTICS

| Description  | Min     | Мах                     |
|--|---------|-------------------------|
| Input voltage with respect to $V_{\rm SS}$ on all pins except I/O pins (including A9, OE#, and RESET#) | –1.0 V  | 11 V                    |
| Input voltage with respect to $V_{SS}$ on all I/O pins   | –1.0 V  | V <sub>CC</sub> + 1.0 V |
| V <sub>CC</sub> Current  | –100 mA | +100 mA                 |

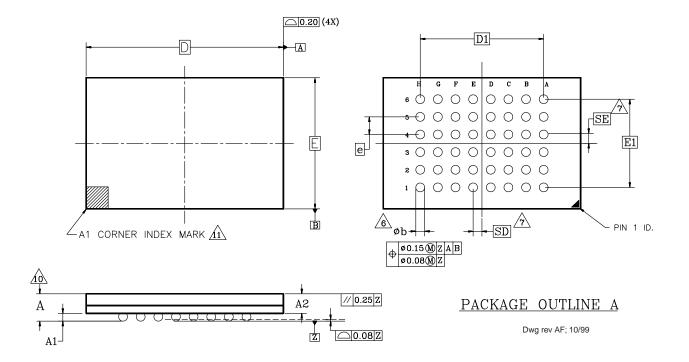

**Note:** Includes all pins except  $V_{CC}$ . Test conditions:  $V_{CC}$  = 2.0 V, one pin at a time.

## DATA RETENTION

| Parameter Description               | Test Conditions | Min | Unit  |
|-------------------------------------|-----------------|-----|-------|
| Minimum Pattern Data Retention Time | 150°C           | 10  | Years |
| Minimum Pattern Data Retention Time | 125°C           | 20  | Years |

#### NOTES:

- 1. DIMENSIONING AND TOLERANCING PER ASME Y14.5M-1994.
- 2. ALL DIMENSIONS ARE IN MILLIMETERS.
- 3. BALL POSITION DESIGNATION PER JESD 95-1, SPP-010.
- 4. e REPRESENTS THE SOLDER BALL GRID PITCH.
- 5. SYMBOL "MD" IS THE BALL ROW MATRIX SIZE IN THE "D" DIRECTION. SYMBOL "ME" IS THE BALL COLUMN MATRIX SIZE IN THE "E" DIRECTION. N IS THE MAXIMUM NUMBER OF SOLDER BALLS FOR MATRIX SIZE MD x ME.
- DIMENSION "b" IS MEASURED AT THE MAXIMUM BALL DIAMETER IN A PLANE PARALLEL TO DATUM Z.
- $\overline{7}$  SD AND SE ARE MEASURED WITH RESPECT TO DATUMS A AND B AND DEFINE THE POSITION OF THE CENTER SOLDER BALL IN THE OUTER ROW. WHEN THERE IS AN ODD NUMBER OF SOLDER BALLS IN THE OUTER ROW PARALLEL TO THE D OR E DIMENSION, RESPECTIVELY, SD OR SE = 0.000 WHEN THERE IS AN EVEN NUMBER OF SOLDER BALLS IN THE OUTER ROW, SD OR SE =  $\overline{|e/2|}$
- 8. "X" in the package variations denotes part is under qualification.
- 9. "+" IN THE PACKAGE DRAWING INDICATE THE THEORETICAL CENTER OF DEPOPULATED BALLS.
- 10 FOR PACKAGE THICKNESS A IS THE CONTROLING DIMENSION.
- A1 CORNER TO BE IDENTIFIED BY CHAMFER, INK MARK, METALLIZED MARKINGS INDENTION OR OTHER MEANS.

# 

## **REVISION SUMMARY**

#### Revision A (November 9, (2000)

Initial release.

#### Revision A+1 (November 8, 2004)

Global

Added cover page

Added Colophon

Updated Trademark

Added referenced links.

#### **Ordering Information**

Added temperature range for Pb-free Packages

#### Valid Combinations for FBGA Packages

Added new order number information

Added new Package Marking information

#### Colophon

The products described in this document are designed, developed and manufactured as contemplated for general use, including without limitation, ordinary industrial use, general office use, personal use, and household use, but are not designed, developed and manufactured as contemplated (1) for any use that includes fatal risks or dangers that, unless extremely high safety is secured, could have a serious effect to the public, and could lead directly to death, personal injury, severe physical damage or other loss (i.e., nuclear reaction control in nuclear facility, aircraft flight control, air traffic control, mass transport control, medical life support system, missile launch control in weapon system), or (2) for any use where chance of failure is intolerable (i.e., submersible repeater and artificial satellite). Please note that Spansion LLC will not be liable to you and/or any third party for any claims or damages arising in connection with above-mentioned uses of the products. Any semiconductor devices have an inherent chance of failure. You must protect against injury, damage or loss from such failures by incorporating safety design measures into your facility and equipment such as redundancy, fire protection, and prevention of over-current levels and other abnormal operating conditions. If any products described in this document represent goods or technologies subject to certain restrictions on export under the Foreign Exchange and Foreign Trade Law of Japan, the US Export Administration Regulations or the applicable laws of any other country, the prior authorization by the respective government entity will be required for export of those products.
